April 28, 2017 0 / 22

A few remarks about Chris.

Talk by Martin Roček for Chris Hull's 60'th WZW-models in (2,2) Superspace

(2,2) σ -model description of bihermitian geometry

Three types of (2, 2) superfields:

 \bullet chiral superfields $\phi,\bar\phi$ satisfying

$$ar{D}_+\phi=0, \quad ar{D}_-\phi=0, \ D_+ar{\phi}=0, \quad D_-ar{\phi}=0,$$

• twisted chiral superfields $\chi,\bar{\chi}$ satisfying

$$ar{D}_+\chi=0, \quad D_-\chi=0, \ D_+ar{\chi}=0, \quad ar{D}_-ar{\chi}=0,$$

• left and right semichiral superfields $\ell, \bar{\ell}, r, \bar{r}$ satisfying

$$ar{D}_+ \ell = 0, \quad ar{D}_- r = 0, \ D_+ ar{\ell} = 0, \quad D_- ar{r} = 0.$$

Action in (2,2) superspace

$$I = \int d^2 \sigma \, d^4 \theta \, K = \int d^2 \sigma \, D^2 \bar{D}^2 K(\ell, \bar{\ell}, r, \bar{r}, \phi, \bar{\phi}, \chi, \bar{\chi})$$

The generalized Kähler potential K is defined modulo generalized Kähler transformations

$$K \mapsto K + f(\ell, \phi, \chi) + \bar{f}(\bar{\ell}, \bar{\phi}, \bar{\chi}) + g(r, \phi, \bar{\chi}) + \bar{g}(\bar{r}, \bar{\phi}, \chi),$$

< ロ > < 同 > < 三 > < 三

K fully encodes the local geometry of the target manifold, which consists of the structures (G, H, J_+, J_-)

• J_{\pm} two integrable complex structures, g bihermitian:

$$J_{\pm}^2 = -1, \quad N(J_{\pm}) = 0$$

 $G(J_{\pm}X, J_{\pm}Y) = G(X, Y).$

H = d^c₊ω₊ = -d^c₋ω₋, dH = 0, ⇔ ∇^(±)J_± = 0 where d^c_± are d^c operators with respect to J_±, and ω_± = GJ_± are hermitian 2-forms.
 Bihermitian structure (discovered with Chris), is equivalent to generalized Kähler geometry.

▲ロト ▲圖ト ▲画ト ▲画ト 三直 - のへで

Three Poisson structures:

$$\pi_{\pm} = (J_+ \pm J_-)G^{-1}$$
, $\sigma = [J_+, J_-]G^{-1}$.

Superfields ϕ, χ, ℓ, r may be interpreted as coordinates adapted to these Poisson structures.

Note: ℓ , r coordinates involve a choice of polarization; K generates canonical transformations from holomorphic coordinates for J_+ to holomorphic coordinates for J_- :

$$J_{+} : \phi, \chi, \ell, \tilde{\ell} := \frac{\partial K}{\partial \ell} , J_{-} : \phi, \bar{\chi}, r, \tilde{r} := \frac{\partial K}{\partial r}$$

Maps from (super)-surface Σ to Lie group **G**. (1,1) superspace action:

$$\begin{split} kI[g] &= -\frac{k}{\pi} \int_{\Sigma} d^2 \sigma \, d^2 \theta \, \operatorname{tr}(g^{-1} \nabla_+ g g^{-1} \nabla_- g) \\ &- \frac{k}{\pi} \int_{B} d^3 \tilde{\sigma} \, d^2 \theta \, \operatorname{tr}(\tilde{g}^{-1} \partial_t \tilde{g} \{ \tilde{g}^{-1} \nabla_+ \tilde{g}, \tilde{g}^{-1} \nabla_- \tilde{g} \}) \end{split}$$

k is an integer, $\Sigma = \partial B$, \tilde{g} is an extension of g from Σ to B.

< ロ > < 同 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 > < 0 >

A. Sevrin: all even dimensional reductive Lie groups super WZW-models have 2, 2 supersymmetry.

On the Lie algebra, \mathbb{J}_{\pm} are given by a choice of Cartan subalgebra and positive direction and both are +i on the positive and -i on the negative roots.

Since any two Cartan decompositions of a Lie algebra are related by group conjugation, the only freedom lies in the choice of the action on the Cartan subalgebra.

Choice of \mathbb{J}_+ and \mathbb{J}_- on the Lie algebra fixes the superfield content or type.

$$N_c = \dim_{\mathbb{C}} \ker(J_+ - J_-), \quad N_t = \dim_{\mathbb{C}} \ker(J_+ + J_-)$$

computed from ker $(J_+ \pm J_-) \sim \text{ker}(\mathbb{J}_+ \pm e_L e_R^{-1} \mathbb{J}_- e_R e_L^{-1})$, where $e_L e_R^{-1}$ is a group element. This gives $(\dim_{\mathbb{C}} \mathbf{G} - N_c - N_t)/2$ semichiral superfields.

Of the $\mathbf{G}_L \times \mathbf{G}_R$ Kac-Moody symmetries of the WZW model, only the Cartan torus subgroup $\mathbf{H}_L \times \mathbf{H}_R$ preserves both complex structures.

T-duality along a Kac-Moody isometry does not change the metric and torsion of a sigma model, but does change the type of the generalized geometry.

Thus, T-duality along a left (or right) isometry *relates the different generalized Kähler structures* on a given Lie group, and can be used to find the different generalized Kähler potentials.

イロト イポト イヨト イヨト 二日

Though we have known how to write WZW-models in (1,1) superspace for a long time, and understood bihermitian geometry in (2,2) superspace for a long time, combining them has proved challenging.

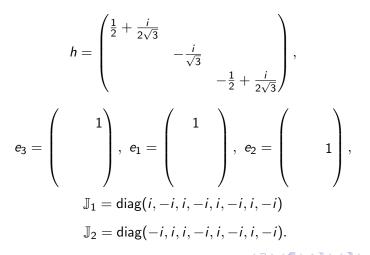

The only cases understood before this work were the WZW-models on $SU(2) \times U(1)$ and $SU(2) \times SU(2)$.

The general case is still difficult, though the approach should be useful for many cases.

SU(3) WZW-model

In the basis $h, \bar{h}, e_3, \bar{e}_3, e_1, \bar{e}_1, e_2, \bar{e}_2$, with

If we choose J_{\pm} equal to each other at the origin, we find type (0,0) at generic points.

If we choose one to be \mathbb{J}_1 and the other \mathbb{J}_2 , we find type (1,1).

イロト イポト イヨト イヨト

Given J_{\pm} at the origin, we find them anywhere by a left or right group action.

Since we know what the holomorphic/anti-holomorphic coordinates are at the origin, we also find them anywhere.

The J_{\pm} holomorphic coordinates take the simplest form when presented in an overcomplete basis,

$$\begin{split} z^{\phi}_{+} &= \log \bar{g}^{\bar{\omega}}_{31} g^{\omega}_{13}, \qquad z^{\chi}_{+} = \log \bar{g}^{\bar{\omega}}_{11} g^{\omega}_{33}, \qquad z^{1}_{+} = \log \frac{g_{13}}{g_{23}}, \\ z^{2}_{+} &= \log \frac{g_{23}}{g_{33}}, \qquad z^{3}_{+} = \log \frac{\bar{g}_{11}}{\bar{g}_{21}}, \qquad z^{4}_{+} = \log \frac{\bar{g}_{21}}{\bar{g}_{31}} \\ z^{\phi}_{-} &= \log \bar{g}^{\omega}_{31} g^{\bar{\omega}}_{13}, \qquad z^{\bar{\chi}}_{-} = \log g^{\bar{\omega}}_{11} \bar{g}^{\omega}_{33}, \qquad z^{1}_{-} = \log \frac{g_{11}}{g_{12}}, \\ z^{2}_{-} &= \log \frac{g_{12}}{g_{13}}, \qquad z^{3}_{-} = \log \frac{\bar{g}_{31}}{\bar{g}_{32}}, \qquad z^{4}_{-} = \log \frac{\bar{g}_{32}}{\bar{g}_{33}}, \end{split}$$

(日) (周) (三) (三)

where $\omega = e^{i\pi/3}$. These coordinates satisfy the relations

$$e^{z_{\pm}^{1}+z_{\pm}^{3}} + e^{-z_{\pm}^{2}-z_{\pm}^{4}} + 1 = 0$$

$$z_{+}^{\phi} - z_{+}^{\chi} = \omega(z_{+}^{1}+z_{+}^{2}) - \bar{\omega}(z_{+}^{3}+z_{+}^{4})$$

$$z_{-}^{\phi} - z_{-}^{\bar{\chi}} = -\bar{\omega}(z_{-}^{1}+z_{-}^{2}) + \omega(z_{-}^{3}+z_{-}^{4})$$

Talk by Martin Roček for Chris Hull's 60'th WZW-models in (2,2) Superspace

For the type (0,0) generalized Kähler structure, SU(3) is parametrized by two sets of semichiral coordinates. Then the Poisson structures are invertible at generic points.

One choice of Darboux semichiral coordinates σ :

$$\sigma(d\ell^{j}, d\tilde{\ell}^{k}) = \delta^{jk} , \ \sigma(d\ell^{j}, d\ell^{k}) = \sigma(d\tilde{\ell}^{j}, d\tilde{\ell}^{k}) = 0$$

$$\sigma(dr^{j}, d\tilde{r}^{k}) = \delta^{jk} , \ \sigma(dr^{j}, dr^{k}) = \sigma(d\tilde{r}^{j}, d\tilde{r}^{k}) = 0$$

is given by

Explicit coordinates

$$\ell^{1} = \frac{1}{3}(z_{+}^{\chi} + 2z_{+}^{\phi} - \omega z_{+}^{1} + \bar{\omega} z_{+}^{4})$$

$$\tilde{\ell}^{1} = (\bar{\omega} - \omega)(z_{+}^{1} + z_{+}^{2} + z_{+}^{3} + z_{+}^{4})$$

$$\ell^{2} = z_{+}^{\chi} , \quad \tilde{\ell}^{2} = z_{+}^{\phi}$$

$$\tilde{r}^{1} = (\bar{\omega} - \omega)(z_{-}^{1} + z_{-}^{2} + z_{-}^{3} + z_{-}^{4})$$

$$r^{1} = \frac{1}{3}(z_{-}^{\bar{\chi}} + 2z_{-}^{\phi} + \bar{\omega} z_{-}^{2} - \omega z_{-}^{3})$$

$$\tilde{r}^{2} = z_{-}^{\bar{\chi}} , \quad r^{2} = z_{-}^{\phi}$$

Many other choices are possible.

April 28, 2017 18 / 22

Image: A match a ma

Integrability

To find the potential, we need to express the $\tilde{\ell}^j$, \tilde{r}^j in terms of ℓ^j , $\bar{\ell}^j$, r^j , \bar{r}^j . The integrability condition

$$d(\theta_1 + \theta_2) = 0 , \quad \theta_j := \tilde{\ell}^j d\ell^j + \bar{\tilde{\ell}}^j d\bar{\ell}^j - \tilde{r}^j dr^j - \bar{\tilde{r}}^j d\bar{r}^j \qquad (\text{no sum})$$

guarantees the existence of a local potential $K(\ell^j, \bar{\ell}^j, r^j, \bar{r}^j)$ generating the symplectomorphism

$$\begin{aligned} \frac{\partial K}{\partial \ell j} &= \tilde{\ell}^{j}, & \frac{\partial K}{\partial \bar{\ell}^{j}} &= \bar{\ell}^{j}, \\ \frac{\partial K}{\partial r^{j}} &= -\tilde{r}^{j}, & \frac{\partial K}{\partial \bar{r}^{j}} &= -\bar{\bar{r}}^{j}. \end{aligned}$$

イロト 不得下 イヨト イヨト 二日

K is given formally by

$$K = \int_{\mathcal{O}}^{(\ell^{j}, \bar{\ell}^{j}, r^{j}, \bar{r}^{j})} \theta_{1} + \theta_{2},$$

where O is some base point. The integrability condition guarantees that the above expression is independent of integration path.

(日) (同) (三) (三)

Once we find, e.g., action of the left Cartan torus on these coordinates (or any others related by different choice of polarization), we can use T-duality to find the K for type (1,1). Open problems include:

- Extending this to the most general case.
- In the $SU(2) \times U(1)$ and $SU(2) \times SU(2)$ cases, dilogarithms arise; can we do the integrals for SU(3) and higher cases?
- Understanding the case with (4,4) supersymmetry.
